I network di ricerca in Medicina del Lavoro: esperienze, opportunità e prospettive

Pre-
pandemic

Post-
pandemic

Comitato scientifico

Coordinatore: Prof. Pietro Apostoli

Componenti e specifiche aree tematiche:

Prof.ssa Valentina Bollati, area della medicina molecolare occupazionale e degli stili di vita

Prof. Massimo Corradi, area clinica e strumenti di sorveglianza sanitaria

Prof. Stefano Mattioli, metodologie investigative su malattie lavoro correlate

Prof. Ivo Iavicoli, area tossicologica

Prof. Sergio Iavicoli, area rischi psicosociali

Prof. Paolo Boffetta, epidemiologia

Prof. Jos Verbeeck, medicina del lavoro basata sulle prove di efficacia

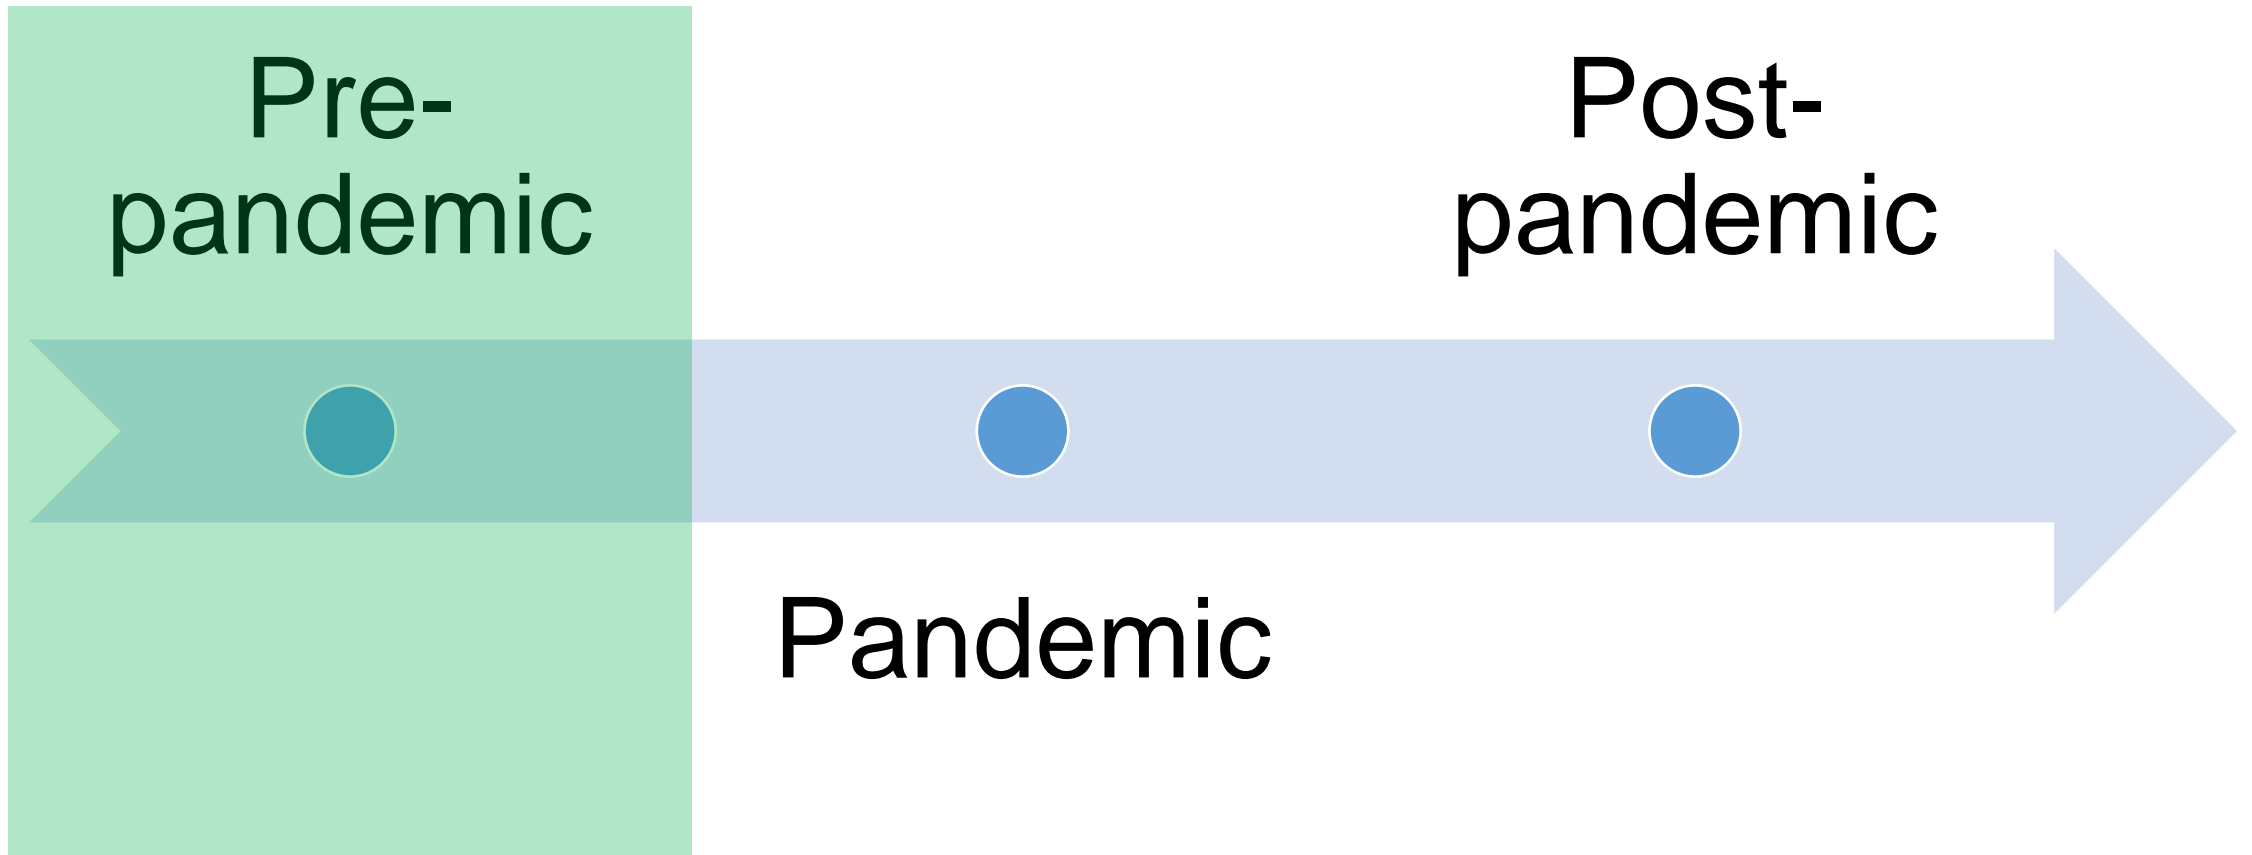

Prof. Alfonso Cristaudo, strumenti di qualificazione ed aggiornamento

Prof. Paolo Durando, area rischio biologico

Prof. Francesco Saverio Violante, area patologie muscoloscheletriche

I network di ricerca in Medicina del Lavoro

I NETWORK NELLA RICERCA IN MEDICINA DEL LAVORO:

UNA PRATICA OBBLIGATA PER LA CRESCITA COMPLESSIVA DELLA NOSTRA DISCIPLINA

Gruppi di lavoro

(Delibera C.D.N. 16/06/2016)

I Gruppi di lavoro attualmente operanti sono 10 (più uno ulteriore approvato nel corso dell'ultimo Consiglio Direttivo).

Sono elencati di seguito:

Ruolo del medico del lavoro nella gestione e prevenzione della tubercolosi in ambito occupazionale.

Coordinatore:

Paolo Durando

Membri:

Massimo Corradi
Monica Lamberti
Vittorio Lodi
Alberto Matteelli
Vincenzo Nicosia
Giantommaso Pagliaro
Donatella Placidi
Giovanni Sotgiu
Maria Gabriella Verso
Guglielmo Dini
Nicola Luigi Bragazzi
Valentina Marchese
Alfredo Montecucco
Alborz Rahmani

Occupational risk factors for multiple sclerosis: a systematic review with meta-analysis

Bruno Kusznir Vittori^{1,2}, Alfredo Alborz Rahmani^{1,2}, Guglielmo Dini^{1,2}, Nicoletta Debarberi^{1,2}, Maria Alberta Benedetta Persechino^{1,2}, Giuliana Buresti^{1,2}

Department of Health Sciences, University of Campania Luigi Vanvitelli, Italy
Occupational Medicine and Public Health, University of Campania Luigi Vanvitelli, Italy

Objective: We decided to conduct a systematic review to identify the occupational risk factors for Multiple Sclerosis (MS).
Methods: A systematic, comprehensive search of electronic academic databases. We included working-age subjects and compared the occurrence of MS. The quality of the included studies was assessed using the Joanna Briggs Institute. All the selected studies were included in the meta-analysis. Heterogeneity was assessed using the I² test. The pooled risk ratio (RR) and 95% confidence interval (CI) were calculated using the random-effects model. The publication bias was assessed using the Egger's test.

Results: Overall, the total sample size was 10,234. The pooled RR for occupational risk factors was 1.21 (95% CI = 1.12–1.31). The pooled RR for agricultural workers was 1.31 (95% CI = 1.12–1.54). The pooled RR for low-income workers was 1.12 (95% CI = 1.02–1.23). The pooled RR for low-income workers was 1.12 (95% CI = 1.02–1.23). The pooled RR for low-income workers was 1.12 (95% CI = 1.02–1.23).

Conclusion: Our study highlights the importance of occupational risk factors in the development of MS. The pooled RR for occupational risk factors was 1.21 (95% CI = 1.12–1.31). The pooled RR for agricultural workers was 1.31 (95% CI = 1.12–1.54). The pooled RR for low-income workers was 1.12 (95% CI = 1.02–1.23). The pooled RR for low-income workers was 1.12 (95% CI = 1.02–1.23).

Systematic review registration: PROSPERO, CRD42022325427.

Keywords: multiple sclerosis, occupational risk factors, epidemiology, etiology.

Introduction
Multiple Sclerosis (MS) is a chronic autoimmune disease characterized by inflammation and demyelination of the central nervous system. The global prevalence of MS is approximately 2.1 (1). The global prevalence of MS is approximately 2.1 (1). The global prevalence of MS is approximately 2.1 (1).

Occupational outcomes of people with multiple sclerosis during the COVID-19 pandemic: a systematic review with meta-analysis

I risultati del progetto, ottenuti utilizzando un approccio metodologico caratterizzato da elevato rigore scientifico, contribuiranno ad aggiornare lo stato delle conoscenze relativamente alle criticità e alle opportunità per la tutela della salute in lavoratori affetti da SM in ambito occupazionale, fornendo spunto per ulteriori progetti di ricerca sulle principali tematiche identificate da implementare nell'ambito di riferimento. In particolare, diversi risultati raggiunti andranno a configurarsi quale solido supporto razionale alle attività che saranno intraprese dallo specifico **gruppo di lavoro multidisciplinare sulla tematica 'SM e lavoro'** la cui composizione è stata **approvata a novembre 2022 dal Consiglio direttivo nazionale della Società italiana di medicina del lavoro (SIML)**.

I NETWORK NELLA RICERCA IN MEDICINA DEL LAVORO:

UNA PRATICA OBBLIGATA PER LA CRESCITA COMPLESSIVA DELLA NOSTRA DISCIPLINA

WHO Health in the World of Work Network

The H-WoW Network is a cross-departmental initiative between Health and Multilateral Partnerships, Global Infectious Hazards Preparedness and Environment, Climate Change and Health.

The initiative follows the World of Work Dialogue in December 2020 which took stock of lessons learned from COVID-19 for future epidemic and pandemic preparedness.

WHO convenes the Health in the World of Work Network with the **goal to increase access to accurate and relevant information and build a community of collaborative sharing** on topics related to health emergency preparedness and response and the **intersection between public health and the workplace.**

Prevention, identification and management of health worker infection in the context of COVID-19

Interim guidance
30 October 2020

Key points

- Health workers in contact with and/or who care for COVID-19 patients are at a higher risk of infection than the general population. Mitigating and reducing this risk is essential to protecting their well-being and reducing the spread of COVID-19.
- Available scientific evidence suggests that appropriate personal protective equipment use, hand hygiene best practices, implementation of universal masking policies in health care facilities and adequate infection prevention and control (IPC) training and education are associated with decreased risk of COVID-19 among health workers.
- The prevention of SARS-CoV-2 infections in health workers requires a multi-pronged integrated approach that includes occupational health and safety (OHS) measures as well as IPC. All health-care facilities should establish or strengthen and implement (a) IPC programmes and (b) Occupational Health and Safety programmes with protocols to ensure HW safety and prevent HW infections while in the work environment. Ensuring adequate clinical staffing levels is recommended to prevent the transmission of health care-associated infections.
- Early detection of SARS-CoV-2 infection among health workers can be achieved through syndromic surveillance and/or laboratory testing and is a key strategy to prevent secondary transmission from health workers to patients, between health workers throughout health-care settings and from health workers to contacts outside of health facilities. A national and/or local surveillance and testing strategy should be developed and implemented.
- A system for managing exposures based on risk assessment should be in place to promote and support health workers' reporting of occupational and non-occupational exposures to or symptoms of COVID-19.
- A system for managing suspected infections, including measures for health workers who test positive for SARS-CoV-2 and those who are

- symptomatic and test negative for SARS-CoV-2, should be in place.
- Clear criteria for returning to work should be established according to the WHO principles for discontinuing isolation for COVID-19.
 - Health systems and facilities should maintain a blame-free culture with regards to COVID-19 infections in health workers.
 - WHO has provided several tools for surveillance and studies to better understand the extent of infections and risk factors for SARS-CoV-2 infection among health workers.

Background

Health workers,¹ in particular those in contact with and/or who care for COVID-19 patients, are at higher risk of being infected with SARS-CoV-2 than the general population.^(1,2) Data collected by the World Health Organization (WHO) global surveillance for COVID-19, primarily from European and American countries, estimate that approximately 14% of COVID-19 cases reported to WHO are among health workers. Transmission of the SARS-CoV-2 virus to health workers has been documented to occur in both acute care and long-term care settings; from patients and residents to health workers as well as among health workers, also potentially associated with exposures to infected co-workers in common areas and break rooms.⁽³⁻⁷⁾

As the pandemic evolves, studies indicate that transmission involving health workers is also occurring in community settings (such as in households) in addition to health care settings.^(6,8-12) COVID-19 infections among health workers may lead to a depleted workforce during a time when the demand on the health care system has increased. In addition, health workers who are infected are at risk of transmitting SARS-CoV-2 virus to others in households and other community settings. For more information on evidence of the epidemiology and risk factors of health worker infections see Box 1. An understanding of the transmission of SARS-CoV-2, as described in the WHO [Transmission of SARS-CoV-2: implications for infection prevention precautions](#)⁽¹⁾ a key element to implementing appropriate infection prevention measures.

social care workers who often have roles in the provision of care in long-term care facilities and in community settings. ⁽⁶⁾

Ministero della Salute

DIREZIONE GENERALE DELLA PREVENZIONE SANITARIA
Ufficio 4

Oggetto: Indicazioni operative relative alle attività del medico competente nel contesto delle misure per il contrasto e il contenimento della diffusione del virus SARS-CoV-2 negli ambienti di lavoro e nella collettività.

La salute e la sicurezza dei luoghi di lavoro vedono coinvolte numerose figure professionali, ciascuna con compiti e responsabilità ben precisi, secondo quanto regolamentato dal D.lgs. 81/2008 e s.m.i.. Il sistema di prevenzione nazionale ed aziendale realizzatosi nel tempo offre la naturale infrastruttura per l'adozione di un **approccio integrato alla valutazione e gestione del rischio connesso all'attuale emergenza pandemica.**

L'attività di prevenzione nei luoghi di lavoro, sia nella fase di "lockdown" sia nella fase di riapertura delle attività produttive sospese in corso di pandemia da SARS-COV 2 ha, con maggiore valenza di sempre, un duplice obiettivo:

- Tutela salute e sicurezza del lavoratore
- Tutela della collettività

Se il ruolo del medico competente risulta di primo piano nella tutela della salute e sicurezza sul lavoro nell'ordinarietà dello svolgimento delle attività lavorative, esso si amplifica nell'attuale momento di emergenza pandemica, periodo durante il quale egli va a confermare il proprio ruolo di "consulente globale" del datore di lavoro.

Luigi De Maria⁷, Antonio Caputi⁷, Stefania Sponselli⁷, Carmine Matrippolito², Carlotta Zunarelli², Giulia Di Felice², Giovanni Visci², Elisa Albini¹⁰, Emanuele Sansone⁵, Cesare Tomasi⁵, Andrea Bisioli⁵, Lorenzo Cipriani⁵, Alessandro De Bellis⁵, Mara Maria Tiraboschi⁵, Emilio Paraggio⁵, Sofia Rubino⁵, Michele Capuzzi⁵, Guglielmo Dini^{3,4}, Bianca Bruzzone⁴, Nicoletta Debarbieri⁴, Alfredo Montecucco^{3,4}, Andrea Orsi^{3,4}, Alborz Rahmani^{3,4}, Valentina Ricucci⁴, Giovanni Guglielmi⁸, Leonardo Fiorentino⁹, Cinzia Brilli⁸, Alessandro Godono⁶, Michael Declémenti⁶, Ihab Mansour⁶, Nicolò Milanese⁶, Giacomo Garzaro⁶, Antonio Scarmozzino¹¹ & Attilia Gullino¹¹

- Given the lack of information on determinants of infection in this important occupational group, and the relevance of such data for other groups of the population, we undertook an **analysis of clinical and occupational data collected among more than 10,000 Italian HCWs** who were tested for presence of SARS-CoV-2 during **March and April 2020**.
- No differences in the risk of infection were detected for job titles**, although there was some heterogeneity in results among centers.
- Working in a COVID-19 designated department was not a risk factor for infection.**
- Contact with a patient was associated with a higher risk of SARS-CoV-2 infection** compared to contact with a colleague, which represented the majority of contacts at the workplace.
- The use of any mask appeared to be the single most effective approach to reduce risk.**
- Strong protection offered by the use of a surgical or FFP2/3 mask by both the HCW and the patient: the effects of the two devices appear to be additive.**

Table 5. Odds ratio of SARS-CoV-2 infection in HCW according to source of contact and use of PPE

Previous infection protected against asymptomatic infection [Relative Risk Ratio (RRR) of recent infection vs no infection 0.53, 95% CI 0.23–1.20] and even more against symptomatic infections [RRR 0.11, 95% CI 0.05–0.25]. Symptomatic infections increased from 70.5% in HW receiving the booster dose since < 64 days to 86.2% when time elapsed was > 130 days.

The risk of breakthrough infections (BI) after booster is significantly reduced by previous infection, heterologous vaccination, and older ages. Immunosuppression is relevant for increased BI incidence. Time elapsed from booster affects BI severity, confirming the public health usefulness of booster.

Fig. 1 Determinants of BI after the booster dose, investigated by a two-level logistic regression model, where level-1 units (HW) were nested into level-2 units (participating centres)

Fig. 2 Determinants of BI investigated by a two-level multinomial logistic regression model (outcome where 0 = no infection, 1 = asymptomatic infection, 2 = symptomatic infection), where level-1 units (health worker) were nested into level-2 units (participating centres)

Duration of SARS-CoV-2 shedding and infectivity in the working age population: a systematic review and meta-analysis

Isolation. Symptomatic or infected persons should isolate promptly, and infected persons should remain in isolation for ≥ 5 days and wear a well-fitting and high-quality mask or respirator if they must be around others. Infected persons may end isolation after 5 days, only when they are without a fever for ≥ 24 hours without the use of medication and all other symptoms have improved, and they should continue to wear a mask or respirator around others at home and in public through day 10^{22,23} (Figure) (22,23).

**I NETWORK NELLA RICERCA IN MEDICINA DEL LAVORO:
UNA PRATICA OBBLIGATA PER LA CRESCITA COMPLESSIVA DELLA NOSTRA DISCIPLINA**

Roles and responsibilities

<https://aiha-assets.sfo2.digitaloceanspaces.com/AIHA/resources/Role-of-the-Industrial-Hygienist-in-a-Pandemic-2nd-edition.pdf>

This includes the following tasks:

- Understanding of aerosol science and respirable pathogens, (i.e., there is no bright line between droplet and airborne transmission of viruses);
- Sources of infection can be controlled through appropriate nose and mouth covers (“face coverings”);
- Face coverings differ from actual respirators that protect highly exposed and vulnerable workers and those with whom they work;
- Need for innovative research in workplace sampling and control of airborne pathogens;
- Need for research and development in the area of occupational limits for biological agents in the workplace.

Lessons learned

- **Industrial hygienists can play a significant role by working with and educating engineers and public health and healthcare personnel**
- **Industrial hygienists can enhance understanding of the exposures and risks associated with pandemic agents, as well as explain how to control those exposures and risks**
- **Industrial hygienists should remember that in a pandemic, the “perfect should not be the enemy of the good”**

I NETWORK NELLA RICERCA IN MEDICINA DEL LAVORO:

UNA PRATICA OBBLIGATA PER LA CRESCITA COMPLESSIVA DELLA NOSTRA DISCIPLINA

Occupational Exposure Banding (OEB)

Occupational Exposure Banding (OEB), sometimes also called Exposure Banding (EB) or hazard banding, is a unique chemical assessment process developed by NIOSH and relies on **hazard-based data to identify the hazard potential** and establish an airborne concentration range for chemicals.

Potential for Future Use: OEBs for Infectious Agents

- It may be possible in the future to utilize OEBs for classification of infectious diseases into exposure bands as additional knowledge regarding the agents' infectious characteristics and more complete toxicological data are published for these illnesses.
- OELs generally have not been published for biological hazards, as there are complex issues in determining an **appropriate OEL**. Some of these issues include lack of appropriate sampling methods, lack of human dose-response information, impact of individual susceptibility, mode of transmission, source/reservoir identification, and lack of viable environmental/ aerosol concentration data for biological agents.
- The use of an OEB with a category concentration modification for environmental surface wipe and infectious aerosol concentrations could address some of these issues. This could be accomplished by allowing **the use of toxicological studies to place causative agents in more or less stringent categories according to infectious potential, virulence, and particle size distribution.**

I NETWORK NELLA RICERCA IN MEDICINA DEL LAVORO:

UNA PRATICA OBBLIGATA PER LA CRESCITA COMPLESSIVA DELLA NOSTRA DISCIPLINA

Provides resources, information, and tools to advise and assist general workers, health care workers, and management to protect workers in the case of a pandemic.

The Role of the Industrial Hygienist in a Pandemic

2nd edition

Roger D. Lewis and Robert Strode, Senior Editors
A publication of the AIHA Biosafety and Environmental Microbiology Committee

Lessons learned

• **Although there are many similarities between chemical, physical, and biological exposure assessments, pandemic agents differ in that:**

- 1) they may be ill-defined in terms of the route of exposure and their stability and viability in the environment;
- 2) the dose required to cause infection may be consistent, but the health effects elicited may be highly variable depending on receptor factors such as age, gender, comorbidities, etc.;
- 3) they lack OELs to guide the industrial hygienist, even when quantitative sampling and analytical methods are available.

• **The predominant mode of transmission of a disease may not be what was originally postulated.** For most pandemics, airborne transmission should not be disregarded simply because droplet and/or contact transmission are known to occur and/or because the airborne transmission is difficult to verify.

• **The concepts of TEH and TWH may be highly applicable during a pandemic** because the hazard is likely to be present in the workplace, at home, and in social environments.

• **The use of occupational exposure banding for biological hazards is in its developmental stages;** however, this process may lead to qualitative and semi-quantitative exposure metrics in the future.

Occupation Risk Rating and Control Options According to Exposure Rank

Control Banding

Exposure = Likelihood x Duration

Likelihood is a surrogate for concentration, the assumption being that the more sources one comes into contact with during the workday, the greater the concentration to which one could be exposed.

| Likelihood | Daily Duration | | |
|-------------------------|----------------------|----------------------|-------------------|
| | D1 (0 to 3 hours) | D2 (3 to 6 hours) | D3 (> 6 hours) |
| L0 (No Exposure) | E0 | E0 | E0 |
| L1 (Exposure Unlikely) | E1 | E1 | E1 |
| L2 (Possible Exposure) | E2 | E2 | E3 |
| L3 (Exposure is Likely) | E2 | E3 | E4 |

Control Band

| Exposure Rank | Control Band |
|---------------|--------------|
| E0 | N |
| E1 | A |
| E2 | B |
| E3 | C |
| E4 | D |

Source, Pathway, Receptor. Note: From "Protecting Essential Workers," Center for Infectious Disease Research and Policy (CIDRAP), 2021. (<https://www.cidrap.umn.edu/covid-19/preparedness-and-response/protecting-essential-workers>).

| | Control Band | Control Options |
|---|--------------|---|
| Aim to lower exposure level Goal: Reduce exposure to E1 levels by selecting additional control strategies from the source and pathway categories and reducing reliance on PPE | A | Source – Do these first |
| | | Pathway – Maybe necessary |
| | | Receptor – Not necessary |
| | B | Source – Do these first, may require multiple options |
| | | Pathway – Do these next, and may require multiple options |
| | | Receptor – Only if source & pathway controls aren't effective |
| | C | Source – Do these first, may require multiple options |
| | | Pathway – Do these next, and may require multiple options |
| | | Receptor – May be prudent |
| | D | Source – Do these first, may require multiple options |
| | | Pathway – Do these next, and may require multiple options |
| | | Receptor – Probably necessary |

Learning from the Experience of the COVID-19 Pandemic: A New Paradigm for Occupational Biohazard Assessment and Management

PAOLO DURANDO^{1,*}, ALBORZ RAHMANI¹, ALFREDO MONTECUCCO¹, GUGLIELMO DINI²

¹Occupational Medicine, Department of Health Sciences, University of Genoa, Genoa, Italy

²Occupational Medicine Unit, IRCCS Ospedale Policlinico San Martino, Genoa, Italy

... it must be stressed that **effective prevention of risk factors for workers' health further requires a multidisciplinary and integrated approach (i.e., between technologists and occupational physicians) during all phases and decision-making process implicated in work.** In this endeavour to provide sound scientific reasoning in all his activities, particularly in the identification of occupational disorders caused by biological hazards, the Occupational Physician should remember, as crystallised in Bradford Hill's nine Points of View, that **no single piece of evidence is sufficient, but that the different types of evidence should be combined** to support the case for causation, as real-world circumstances often differ from those presented in scientific studies. **Only through evidence-based practice approaches for assessing and characterising biological risk will improve, as data emerge and enhance our understanding of exposure and risk management, potentially in all occupational settings.**
